- 1) The example is intended for emissive displays (E). The standard contrast step (bold) C_{Y_5} with $L_{NE} = 4 \text{ cd/m}^2$ may be reached.
2) The computer operating system Apple has used the value 1,8 until 2010. The change to 2,4 (= Windows) is in the wrong direction.
3) For the contrast $C_Y = 36:1$ the viewing luminances of both the black paper and the black on the screen are equal.
Also the viewing luminances of all colours at the screen and the paper are equal, for example for a 16 step grey scale.
For all black surfaces it is valid $Y_N > 2,5$. Therefore high contrast steps are only possible at the displays by reduced reflection.
4) Measurement of 445 (= $500 \cdot 0,889$) lux corresponds to the viewing luminance $L_V = 142 \text{ cd/m}^2$ for an emissive display (E).

A visual fatigue based on an adaptation change between paper and display is excluded.
For all black surfaces it is valid $Y_N > 2,5$. Therefore high contrast steps are only possible at the displays by reduced reflection.

- 1) The example is given for data projectors (P). The standard contrast step (bold) C_{Y_5} with $L_{WP} = 142 \cdot 36 \text{ cd/m}^2$ is hard to reach.
2) The computer operating system Apple has used the value 1,8 until 2010. The change to 2,4 (= Windows) is in the wrong direction.
3) For the contrast $C_Y = 2:1$ the viewing luminances of both the black in the projection and the white standard offset paper are equal (!).
Visual fatigue caused by the adaptation luminance ratio 36:1 of the black at the screen and the black at the paper shall be reduced.
If for example a grey screen with the CIE tristimulus value $Y_Z = 22,2$ (= $0,25 \cdot 88,9$) is used the contrast step C_{Y_1} remains constant.
Then the luminance ratio of all colours at the screen and the paper has reduced to 9:1. This reduces visual fatigue.
